1. (a) Here we first note that on U,

$$(x \circ i) : (x, y) \mapsto (x, 0, 0), \quad (y \circ i) : (x, y) \mapsto (0, y, 0), \quad (z \circ i)(x, y) \mapsto (0, 0, \varphi^{-1}(x, y)_z) = (0, 0, \sqrt{1 - x^2 - y^2})$$

This allows us to calculate

$$i^* dx = d(x \circ i) = dx$$

$$i^* dy = d(y \circ i) = dy$$

$$i^* dz = d(z \circ i) = d(0, 0, \sqrt{1 - x^2 - y^2}) = \frac{\partial}{\partial x} \sqrt{1 - x^2 - y^2} dx + \frac{\partial}{\partial y} \sqrt{1 - x^2 - y^2} dy$$

$$= -\frac{x}{\sqrt{1 - x^2 - y^2}} dx - \frac{y}{\sqrt{1 - x^2 - y^2}} dy$$

(b)

$$i^*(xdx + ydy + zdz) = i^*(xdx) + i^*(ydy) + i^*(zdz)$$

$$= (x \circ i)(i^*dx) + (y \circ i)(i^*dy) + (z \circ i)(i^*dz)$$

$$= xdx + ydy - z\left(\frac{x}{\sqrt{1 - x^2 - y^2}}dx + \frac{y}{\sqrt{1 - x^2 - y^2}}dy\right)dz$$

$$= xdx + ydy - (xdx + ydy) = 0$$

We could have anticipated that this value would be zero, because the evaluation of a tangent vector at a point by this pull back can be seen as taking the dot product of the vector with the point's position vector in  $\mathbb{R}^3$  (see the second line of the calculation above), however, the position vector of a point on the 2-sphere is the radial vector outward from the 2-sphere and thus is perpendicular to the tangent space (plane) of the 2-sphere at that point, hence any vector in the tangent space (plane) of the two-sphere at that point should be orthogonal to the position vector at that point, implying that their dot product should be zero.

**2.** (a)  $\{\alpha, \beta\}$  being the dual frame of  $\{X, Y\}$  is equivalent to

$$\alpha(X) = \beta(Y) = 1$$
 and  $\alpha(Y) = \beta(X) = 0$ 

We solve for X and Y. Firstly, we may write wlog

$$X = u_1 \frac{\partial}{\partial x} + u_2 \frac{\partial}{\partial y}$$
 
$$Y = v_1 \frac{\partial}{\partial x} + v_2 \frac{\partial}{\partial y}$$

Then we get a system of equations for X,

$$\alpha(X) = 1 \iff xu_1 + yu_2 = 1 \tag{1}$$

$$\beta(X) = 0 \iff yu_1 + xu_2 = 0 \tag{2}$$

taking x(1) - y(2) we get  $x^2u_1 - y^2u_1 = x$ , so that  $u_1 = \frac{x}{x^2 - y^2}$ . Substituting this into (2) yields  $u_2 = \frac{-y}{x^2 - y^2}$ . Similarly, we solve for Y with the equations

$$\alpha(Y) = 0 \iff xv_1 + yv_2 = 0 \tag{3}$$

$$\beta(Y) = 1 \iff yv_1 + xv_2 = 1 \tag{4}$$

Then taking y(4) - x(3) we get  $(y^2 - x^2)v_1 = y$  so that  $v_1 = \frac{y}{y^2 - x^2}$ , and finally substituting back into (3),  $v_2 = \frac{-x}{x^2 - y^2}$ . The result is

$$X = \frac{x}{x^2 - y^2} \frac{\partial}{\partial x} - \frac{y}{x^2 - y^2} \frac{\partial}{\partial y} \qquad Y = \frac{y}{y^2 - x^2} \frac{\partial}{\partial x} - \frac{x}{x^2 - y^2} \frac{\partial}{\partial y}$$

It is immediate that by construction the vector fields X,Y satisfy the condition  $\alpha(X)=\beta(Y)=1$  and  $\alpha(Y)=\beta(X)=0$ . Furthermore, these are vector fields on  $\mathbb{R}^2\setminus\{(x,y)|x=\pm y\}$ , since each expression is infinitely differentiable on  $\{(x,y)|x=\pm y\}^c$ .

(b) We first compute that

$$dh = 2xydx + x^2dy$$
 and  $dg = y\cos(xy)dx + x\cos(xy)dy$ 

Then we have that

$$dh \wedge dg = 2xy^2 \cos(xy) dx \wedge dx + 2x^2 y \cos(xy) dx \wedge dy + x^2 y \cos(xy) dy \wedge dx + x^3 \cos(xy) dy \wedge dy$$
$$= (2x^2 y \cos(xy) - x^2 y \cos(xy)) dx \wedge dy = x^2 y \cos(xy) dx \wedge dy$$

**3.** (a) The regular level set theorem, to check that c is indeed a regular value, we have that for any  $p \in f^{-1}(c)$ , that

$$\begin{bmatrix} \frac{\partial}{\partial x} f|_p & \frac{\partial}{\partial y} f|_p & \frac{\partial}{\partial z} f|_p \end{bmatrix} \neq \begin{bmatrix} 0 & 0 & 0 \end{bmatrix}$$

Since the z partial is non-zero by assumption. Note that by the regular level set theorem S has dimension 3-1=2.

(b) Since S has dimension 2, we have that  $i^*\omega \in \Omega^2(S)$  is a top form. To see that it is nowhere vanishing, note that  $df i \equiv 0$  (proof below). Now consider any point  $p \in S$ , we can take  $\{u,v\}$  as a basis for  $T_pS$  where  $di(u) = (x_1, y_1, z_1)$  and  $di(v) = (x_2, y_2, z_2)$ , it follows that neither of  $(x_i, y_i) = (0, 0)$ , otherwise

$$dfi(u) = \frac{\partial}{\partial z} f|_p z_1 \neq 0 \text{ or } dfi(v) = \frac{\partial}{\partial z} f|_p z_2 \neq 0$$

contradicting that  $dfi \equiv 0$ , it follows that  $diu = (x_1, y_1, z_1)$  and  $div = (x_2, y_2, z_2)$  such that

$$(0,0) \neq (x_1, y_1) \neq \lambda(x_2, y_2) \neq (0,0) \quad \forall \lambda \in \mathbb{R}$$

since in the case of  $(x_1, y_1) = \lambda(x_2, y_2)$  we have  $u - \lambda v \neq 0$  (by linear independence of u, v assumed by them being a basis for the two dimensional  $T_pS$ ), so that  $di(u - \lambda v) = (0, 0, z_3)$  for  $z_3 \neq 0$ , so that for the same reasons as above  $df(z_3) \neq 0$ , a contradiction. Now given this characterization of  $T_pS$ , we compute on  $T_pS$ 

$$i^*\omega(u,v) = \omega(d\iota(u),d\iota(v)) = \omega(x_1\frac{\partial}{\partial x} + y_1\frac{\partial}{\partial y} + z_1\frac{\partial}{\partial z}, x_2\frac{\partial}{\partial x} + y_2\frac{\partial}{\partial y} + z_2\frac{\partial}{\partial z})$$

$$= dx \wedge dy(x_1\frac{\partial}{\partial x} + y_1\frac{\partial}{\partial y} + z_1\frac{\partial}{\partial z}, x_2\frac{\partial}{\partial x} + y_2\frac{\partial}{\partial y} + z_2\frac{\partial}{\partial z})$$

$$= x_1y_2 - x_2y_1 = \det\begin{bmatrix} x_1 & x_2 \\ y_1 & y_2 \end{bmatrix} \neq 0 \text{ Since } (x_1, y_1) \notin \text{Span}(x_2, y_2)$$

Which of course proves that for any p, we have  $i^*\omega \not\equiv 0$  on  $T_pS$ .

**Proof that df** $i \equiv \mathbf{0}$ : Consider any  $p \in S$ , let  $u \in T_pS$ , then for some path  $\gamma : (-\epsilon, \epsilon) \to S$ , we have that  $\gamma(0) = p, \gamma'(0) = u$ . Then  $df \iota_p(u) = \frac{d}{dt}|_{t=0} f \iota(\gamma(t))$ , but since  $\gamma(-\epsilon, \epsilon) \subset S$ , we have  $f \iota(\gamma(t)) = c$ ,  $\forall t \in (-\epsilon, \epsilon)$ , hence

$$df \iota_p(u) = \frac{d}{dt}|_{t=0} f \iota(\gamma(t)) = \frac{d}{dt}|_{t=0} c = 0$$

**4.** (a) I claim that  $\lambda = 2z$ , we check this in the z > 0 and x > 0 hemisphere charts, the rest of the charts work similarly. Let  $U = S^2 \cap \{z > 0\}, V = S^2 \cap \{x > 0\}$ , then

$$d\eta = di^* \tilde{\eta} = i^* d\tilde{\eta} = i^* (-dy \wedge dx + dx \wedge dy) = 2i^* (dx \wedge dy) = 2(i^* dx \wedge i^* dy)$$
$$i^* \tilde{\omega} = (x \circ i)i^* (dy \wedge dz) + (y \circ i)i^* (dz \wedge dx) + (z \circ i)i^* (dx \wedge dy)$$
$$= x(i^* dy \wedge i^* dz) + y(i^* dz \wedge i^* dx) + z(i^* dx + i^* dy)$$

In (U,(x,y)) we have coordinates  $(x,y,\sqrt{1-x^2-y^2})\mapsto (x,y)$ , hence by the same computations as in problem 1, we have

$$i^*dx = dx$$
,  $i^*dy = dy$ ,  $i^*dz = -\frac{1}{\sqrt{1 - x^2 - y^2}}(xdx + ydy)$ 

So, in this chart  $d\eta = 2dx \wedge dy$ , and

$$\omega = x(i^*dy \wedge i^*dz) + y(i^*dz \wedge i^*dx) + z(i^*dx + i^*dy)$$

$$= x(dy \wedge -\frac{1}{\sqrt{1 - x^2 - y^2}}(xdx + ydy)) + y(-\frac{1}{\sqrt{1 - x^2 - y^2}}(xdx + ydy) \wedge dx) + \sqrt{1 - x^2 - y^2}dx \wedge dy$$

$$= \frac{x^2}{\sqrt{1 - x^2 - y^2}}(dx \wedge dy) + \frac{y^2}{\sqrt{1 - x^2 - y^2}}(dx \wedge dy) + \sqrt{1 - x^2 - y^2}dx \wedge dy$$

$$= \frac{1}{\sqrt{1 - x^2 - y^2}}dx \wedge dy$$

So that indeed  $\lambda = 2z = 2\sqrt{1-x^2-y^2}$  satisfies  $\lambda \omega = d\eta$ . The closed form for  $\eta$  on x and y hemispheres looks a bit different, so we verify equality on V, then equality on the rest of the hemisphere charts follows similarly. On V we use the same computation as problem 1 due to symmetry of the charts, to find that

$$i^*dx = -\frac{1}{\sqrt{1-x^2-y^2}}(ydy+zdz), \quad i^*dy = dy, \quad i^*dz = dz$$

So that in V, we have

$$d\eta = \frac{-2}{\sqrt{1 - x^2 - y^2}} (ydy + zdz) \wedge dy = \frac{2z}{\sqrt{1 - x^2 - y^2}} dy \wedge dz$$

And the calculation for  $\omega$  is symmetric to the one above, so that

$$\omega = \frac{1}{\sqrt{1 - y^2 - z^2}} dy \wedge dz$$

Verifying that  $\lambda \omega = d\eta$  on V, the rest of the charts are computed similarly to one of U or V.

(b) First note that in the z < 0 hemisphere, we get  $\omega = \frac{-1}{\sqrt{1-x^2-y^2}} dx \wedge dy = \frac{1}{z} dx \wedge dy$ .

We rewrite  $\frac{\partial}{\partial z} = \frac{\partial x}{\partial z} \frac{\partial}{\partial x} + \frac{\partial y}{\partial z} \frac{\partial}{\partial y} = (\frac{\partial z}{\partial x})^{-1} \frac{\partial}{\partial x} + (\frac{\partial z}{\partial y})^{-1} \frac{\partial}{\partial y}$ , in either z > 0 hemisphere coordinates or z < 0 hemisphere coordinates (note we are doing this since z is a function of x, y here) we get that  $\frac{\partial}{\partial z} = -\frac{z}{x} \frac{\partial}{\partial x} - \frac{z}{y} \frac{\partial}{\partial y}$ . Then

$$X = \left(-xz - \frac{z(x^2 + y^2)}{x}\right) \frac{\partial}{\partial x} + \left(-yz - \frac{z(x^2 + y^2)}{y}\right) \frac{\partial}{\partial y}$$
$$= -z\left(\frac{2x^2 + y^2}{x}\right) \frac{\partial}{\partial x} - z\left(\frac{x^2 + 2y^2}{y}\right) \frac{\partial}{\partial y}$$

This allows us to compute dx(X), and dy(X) in either hemispheres coordinates.

$$dx(X) = -z\left(\frac{2x^2 + y^2}{x}\right)$$

$$dy(X) = -z\left(\frac{x^2 + 2y^2}{y}\right)$$

$$dy(Y) = x$$

Now computing  $X \perp \omega$  and  $Y \perp \omega$  by plugging in the above values,

$$\begin{split} X \lrcorner \ \omega &= X \lrcorner \ \frac{1}{z} dx \wedge dy = \frac{1}{z} (dx(X) dy - dy(X) dx) \\ &= \frac{1}{z} (-z \left( \frac{2x^2 + y^2}{x} \right) dy + z \left( \frac{x^2 + 2y^2}{y} \right) dx) \\ &= - \left( \frac{2x^2 + y^2}{x} \right) dy + \left( \frac{x^2 + 2y^2}{y} \right) dx \\ Y \lrcorner \ \omega &= Y \lrcorner \ \frac{1}{z} dx \wedge dy = \frac{1}{z} (dx(Y) dy - dy(Y) dx) \\ &= \frac{1}{z} \left( -y dy - x dx \right) \end{split}$$

Now we compute their wedge product,

$$\begin{split} X \,\lrcorner\, \omega \wedge Y \,\lrcorner\, \omega &= -\left(\frac{2x^2+y^2}{x}\right) dy + \left(\frac{x^2+2y^2}{y}\right) dx \wedge \frac{-1}{z} (y dy + x dx) \\ &= \frac{(2x^2+y^2)}{z} dy \wedge dx - \frac{x^2+y^2}{z} dx \wedge dy \\ &= \frac{-3(x^2+y^2)}{z} dx \wedge dy \end{split}$$

This gives us that  $\phi = -3(x^2 + y^2)$  in either hemispheres coordinates, it is clear that  $\phi \in C^{\infty}(S^2)$ . Since  $X \, \omega \wedge Y \, \omega = \phi \omega$  on either hemisphere, and forms are continuous, it follows that they are also equal on the boundary of the hemispheres. This implies that  $\phi$  is defined this way on all of  $S^2$ , since the definition is valid for z > 0, z < 0, and their boundary being z = 0.
